

# JSP : Java Server Pages

- We need JSP to take care of the **Dynamic Content** and **Personalization**
- We need the web designer to focus on the design of the web page and the programmer to focus on the application logic
- Whatever you can do with Servlet you can do with JSP
- JSP is a way to automate the process of generating responses in HTML format.
- If we didn't have JSP, we had to craft the reply ourselves in Servlet.
- Servlets are good whenever you have heavy-weight computation that requires “real programming”

# Servlets and Java Server pages

- How servlet/jsp will work?

# Simple JSPs

- <http://localhost/jsp-examples/jsp3/f2/index1.jsp>

# Simple JSPs

- In the Browser type:
  - `http://localhost/jsp-examples/jsp3/f2/index1.jsp`
- Normally you would name it as `index1.html`. However this time you save it as `index1.jsp` and place it in your `jsp` directory of `tomcat` and point your browser to
  - `http://localhost/jsp-examples/jsp3/f2/index1.jsp`
- If this were a `html` page the web server simply reads the contents and sent them to the browser
  - `http://localhost/jsp-examples/jsp3/f2/index1.html`

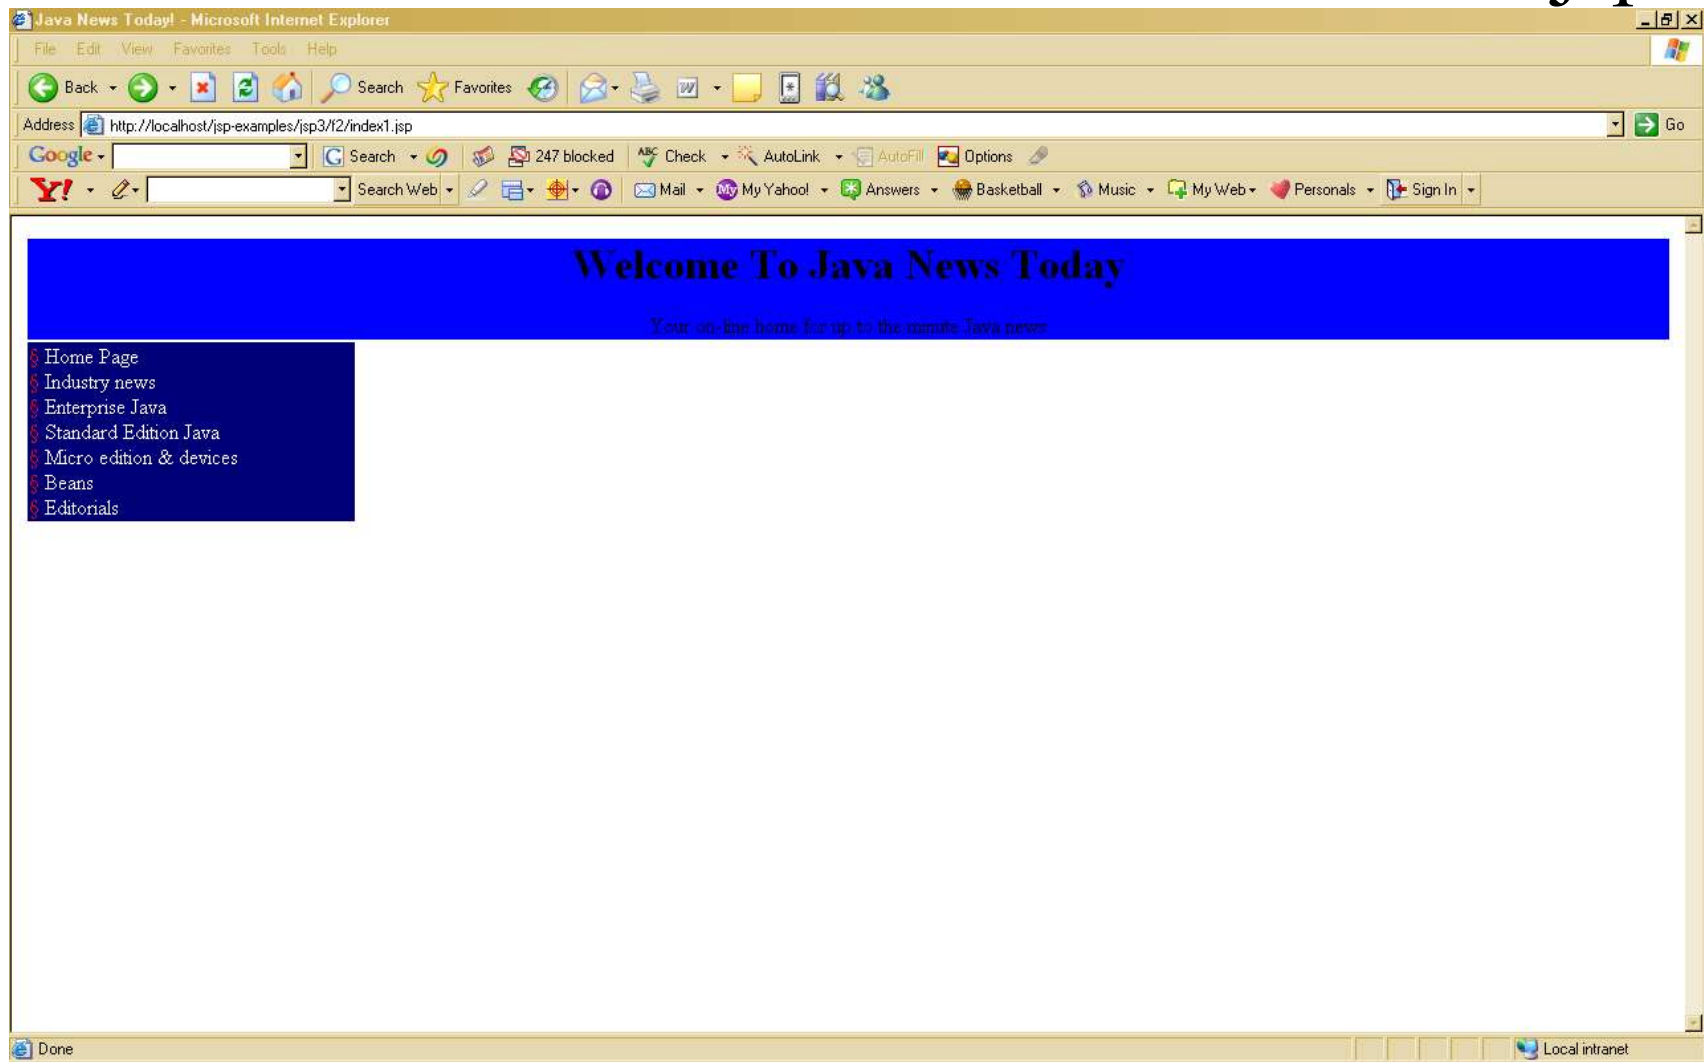

# Simple JSPs

- Here is how it looks like in the browser as index1.html

# Simple JSPs

- Here is how it looks like in the browser as a jsp

# Simple JSPs

- See the Code generated for the JSP

The screenshot displays a Windows file explorer window showing the directory structure of an Apache Tomcat installation. The left pane shows the file explorer view, and the right pane shows the file list. The file list includes files like `index1_jsp.class` (CLASS File, 6 KB) and `index1_jsp` (JAVA File, 6 KB). Below the file explorer, a Notepad window titled `index1_jsp - Notepad` displays the source code of the JSP file. The code is a Java class generated by the Jasper component of Apache Tomcat, implementing `HttpJspBase` and `JspSourceDependent`. The code includes package declarations, imports, and class definitions.

```
/*
 * Generated by the Jasper component of Apache Tomcat
 * Version: Apache Tomcat/7.0.34
 * Generated at: 2013-10-14 02:56:05 UTC
 * Note: The last modified time of this file was set to
 *       the last modified time of the source file after
 *       generation to assist with modification tracking.
 */
package org.apache.jsp.jsp3.f2;

import javax.servlet.*;
import javax.servlet.http.*;
import javax.servlet.jsp.*;

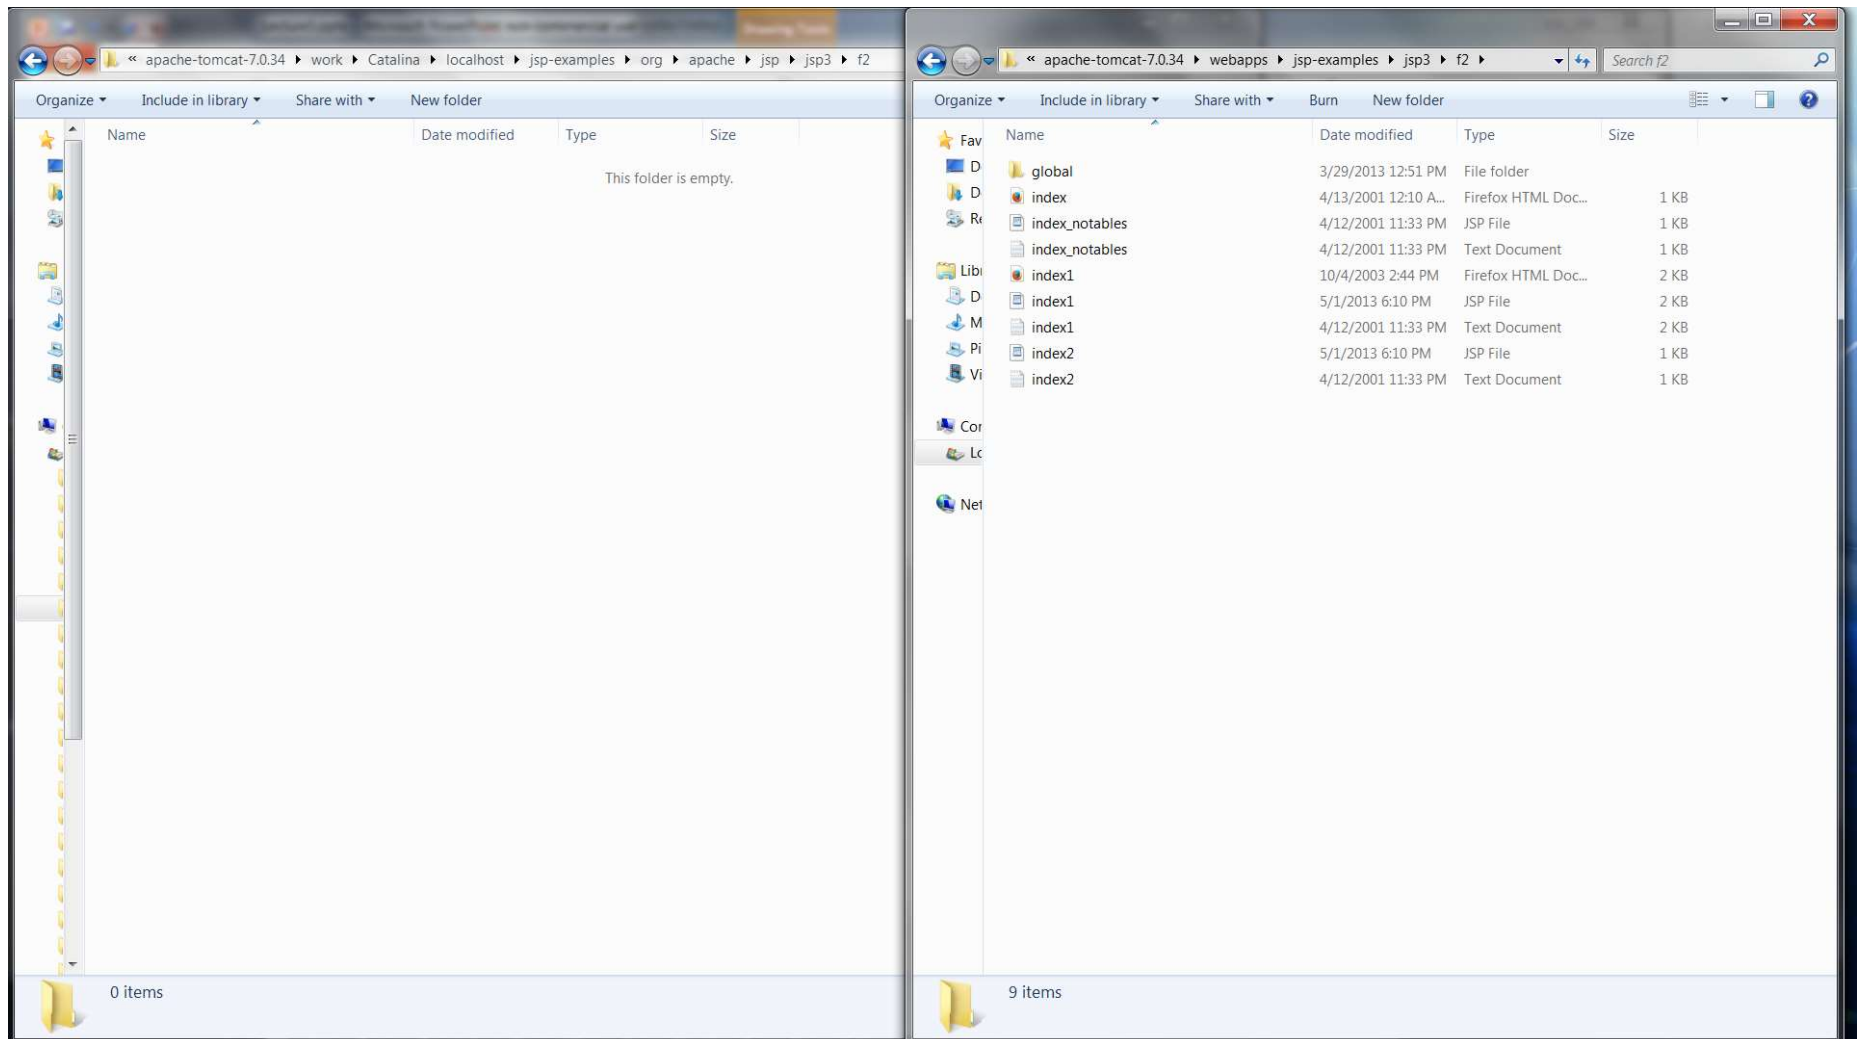

public final class index1_jsp extends org.apache.jasper.runtime.HttpJspBase
    implements org.apache.jasper.runtime.JspSourceDependent {

    private static final javax.servlet.jsp.JspFactory _jspxFactory =
        javax.servlet.jsp.JspFactory.getDefaultFactory();

    private static java.util.Map<java.lang.String,java.lang.Long> ispx_dependants;
```

# Simple JSPs

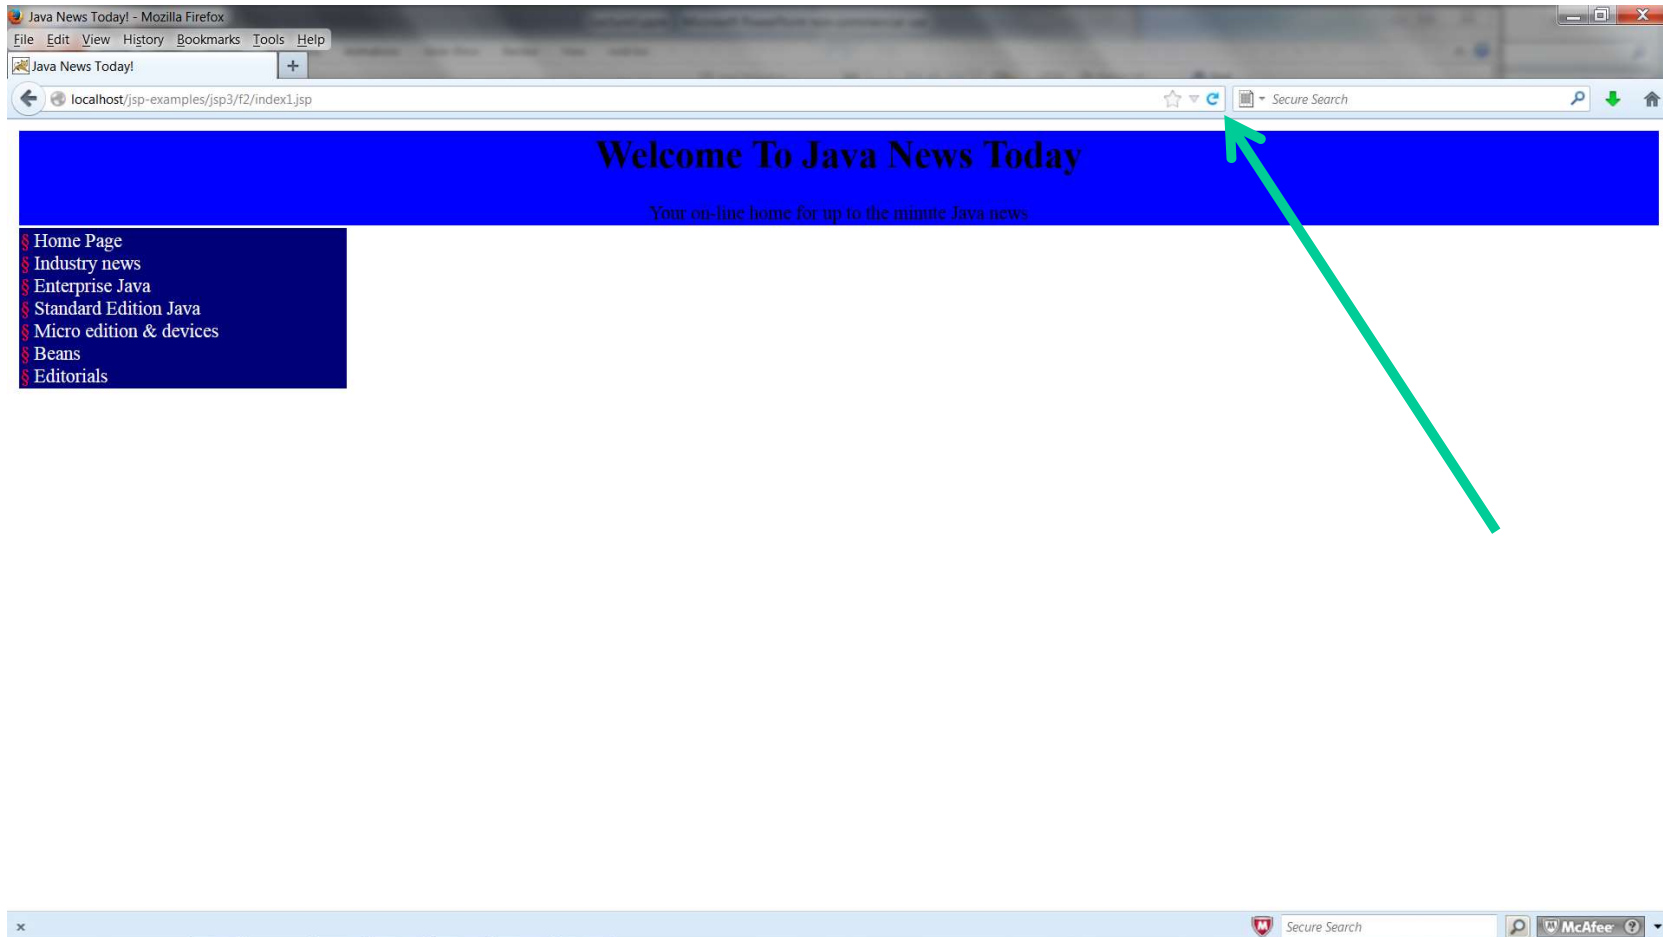

- Delete the Code generated for the JSP manually

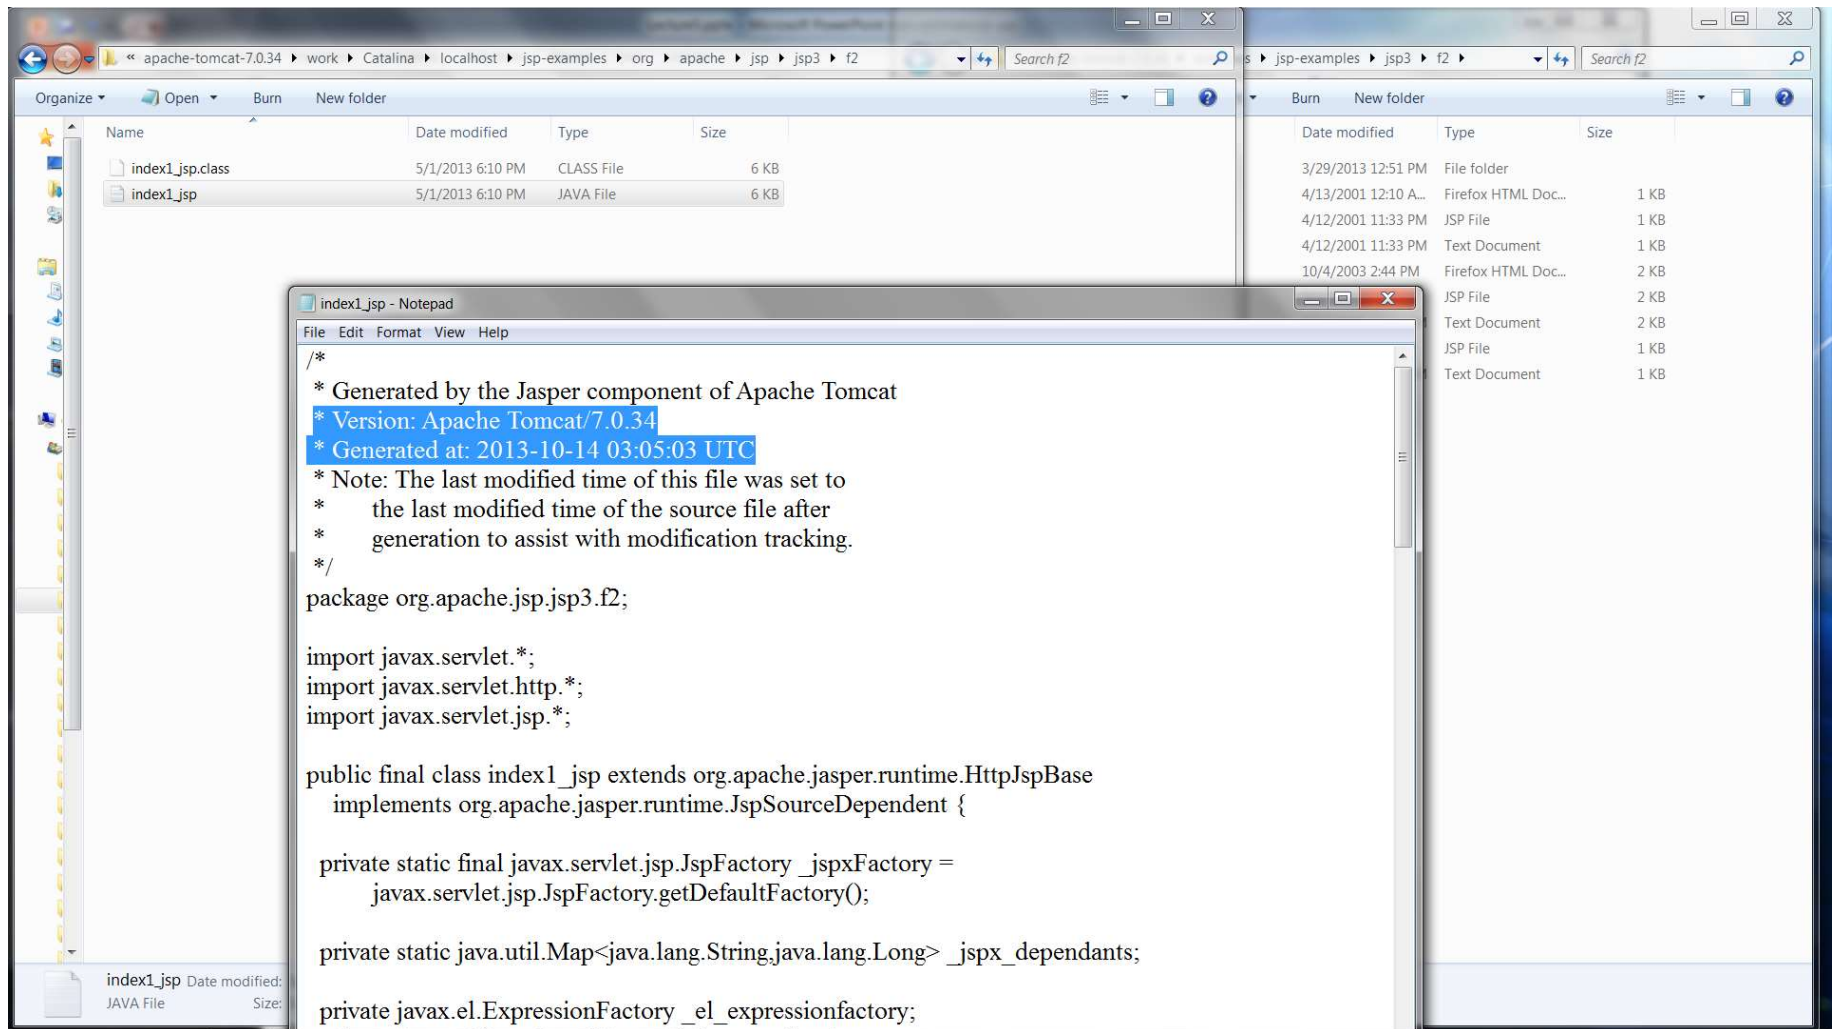

# Simple JSPs

- Reload the browser with index1.jsp to RE-Generate the Code

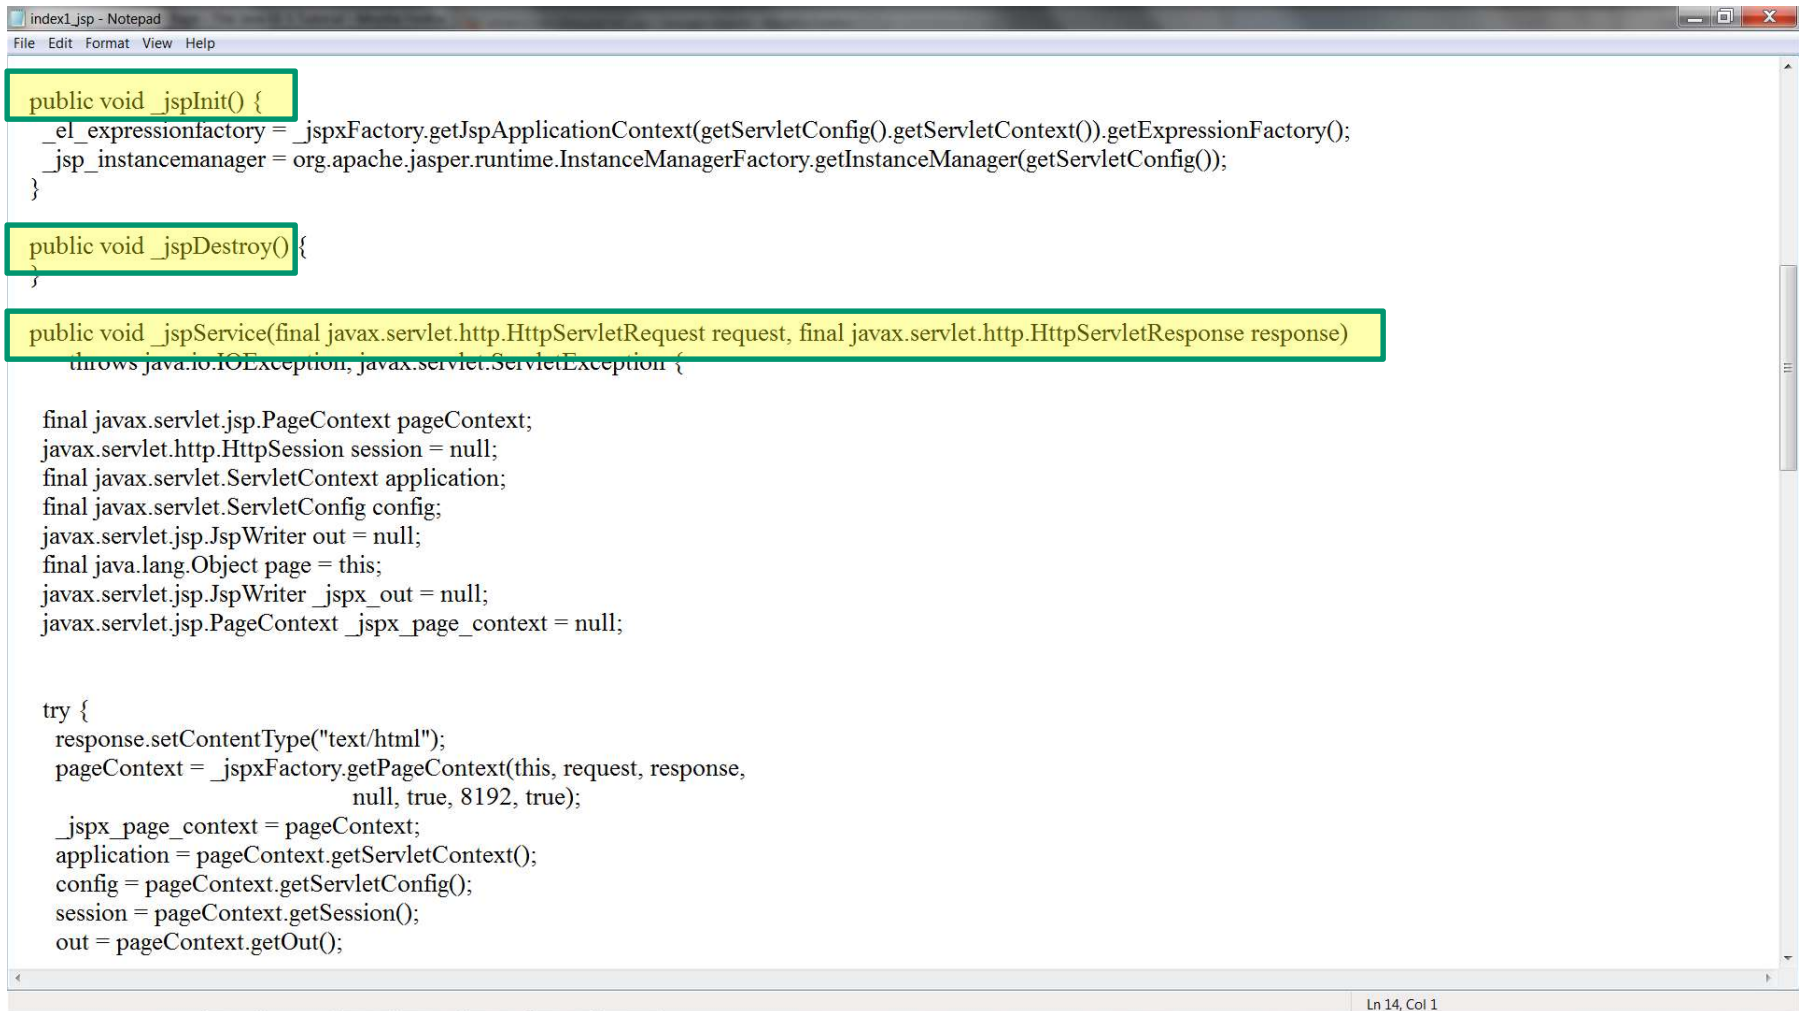

# Simple JSPs

- See the Code generated for the JSP AGAIN

# Simple JSPs

- See the Code generated for the JSP AGAIN

A screenshot of a Notepad window titled 'index1\_jsp - Notepad'. The window contains Java code for a JSP page. The code is organized into three main sections, each highlighted with a yellow background and a green border. The first section is the `_jspInit()` method, which initializes the expression factory and instance manager. The second section is the `_jspDestroy()` method, which is currently empty. The third section is the `_jspService()` method, which handles the request and response. It initializes various objects like `pageContext`, `session`, `application`, `config`, `out`, `page`, `_jspx_out`, and `_jspx_page_context`. It then enters a try block to set the content type to 'text/html' and get the page context, application, config, session, and output writer from the page context.

```
index1_jsp - Notepad
File Edit Format View Help

public void _jspInit() {
    _el_expressionfactory = _jspxFactory.getJspApplicationContext(getServletConfig().getServletContext()).getExpressionFactory();
    _jsp_instancemanager = org.apache.jasper.runtime.InstanceManagerFactory.getInstanceManager(getServletConfig());
}

public void _jspDestroy() {
}

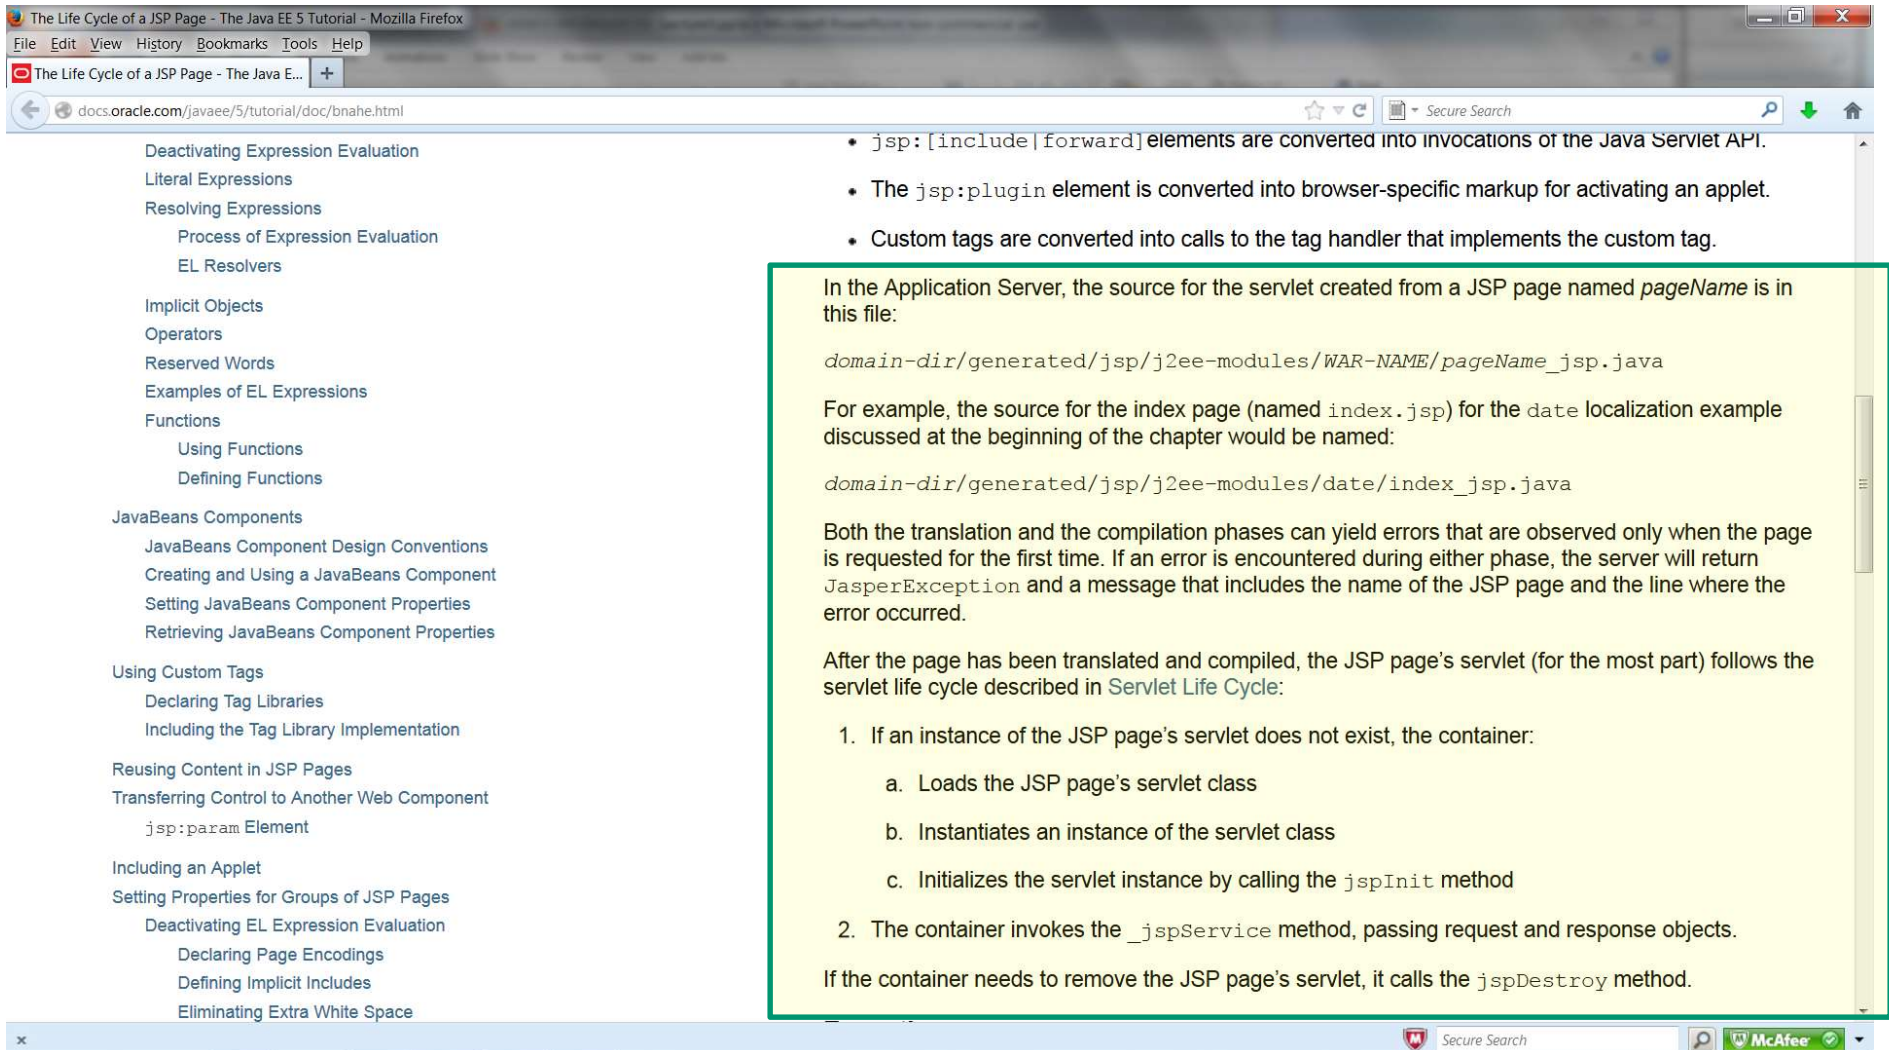

public void _jspService(final javax.servlet.http.HttpServletRequest request, final javax.servlet.http.HttpServletResponse response)
    throws java.io.IOException, javax.servlet.ServletException {

- jsp:[include|forward] elements are converted into invocations of the Java Servlet API.
- The jsp:plugin element is converted into browser-specific markup for activating an applet.
- Custom tags are converted into calls to the tag handler that implements the custom tag.

In the Application Server, the source for the servlet created from a JSP page named *pageName* is in this file:

```
domain-dir/generated/jsp/j2ee-modules/WAR-NAME/pageName_jsp.java
```

For example, the source for the index page (named *index.jsp*) for the date localization example discussed at the beginning of the chapter would be named:

```
domain-dir/generated/jsp/j2ee-modules/date/index_jsp.java
```

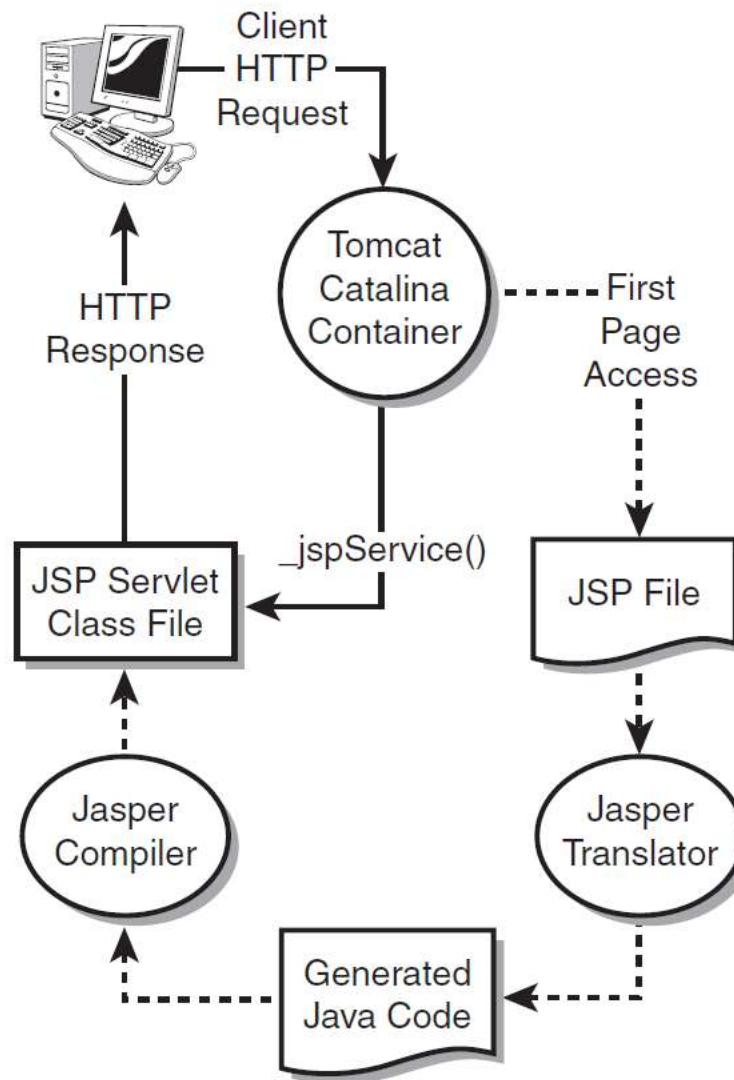

Both the translation and the compilation phases can yield errors that are observed only when the page is requested for the first time. If an error is encountered during either phase, the server will return *JasperException* and a message that includes the name of the JSP page and the line where the error occurred.

After the page has been translated and compiled, the JSP page's servlet (for the most part) follows the servlet life cycle described in *Servlet Life Cycle*:

1. If an instance of the JSP page's servlet does not exist, the container:
  - a. Loads the JSP page's servlet class
  - b. Instantiates an instance of the servlet class
  - c. Initializes the servlet instance by calling the `jspInit` method
2. The container invokes the `_jspService` method, passing request and response objects.

If the container needs to remove the JSP page's servlet, it calls the `jspDestroy` method.

# Tomcat - JSP life cycle

# Simple JSPs

- But since this is a jsp page the web server asks the jsp engine for this page.
- The jsp engine does not directly send the contents, but it converts the jsp into a servlet.
- It then sends a request to the servlet, and the servlet generates a response, which includes the page text, and sends it back to the browser.

# Simple JSPs

- Consider the above example.
- We have used `<!--...-->` for comments. If we use these comments and if the user sees the resulting jsp by view source command then he can see the command.
- The jsp has introduced a special tags for comments `<%--....--%>`. When the jsp engine encounters this it will not send this back to the user.

# Simple JSPs

- In the above example. We have placed code between two comments to separate TWO sections, Header and Navigation:
  - `<!-- Begin Header -->`
  - `<!-- End Header -->`
  - `<!-- Begin Navigation -->`
  - `<!-- End Navigation -->`
- Instead we can use `%@include file="filename.jsp"`.

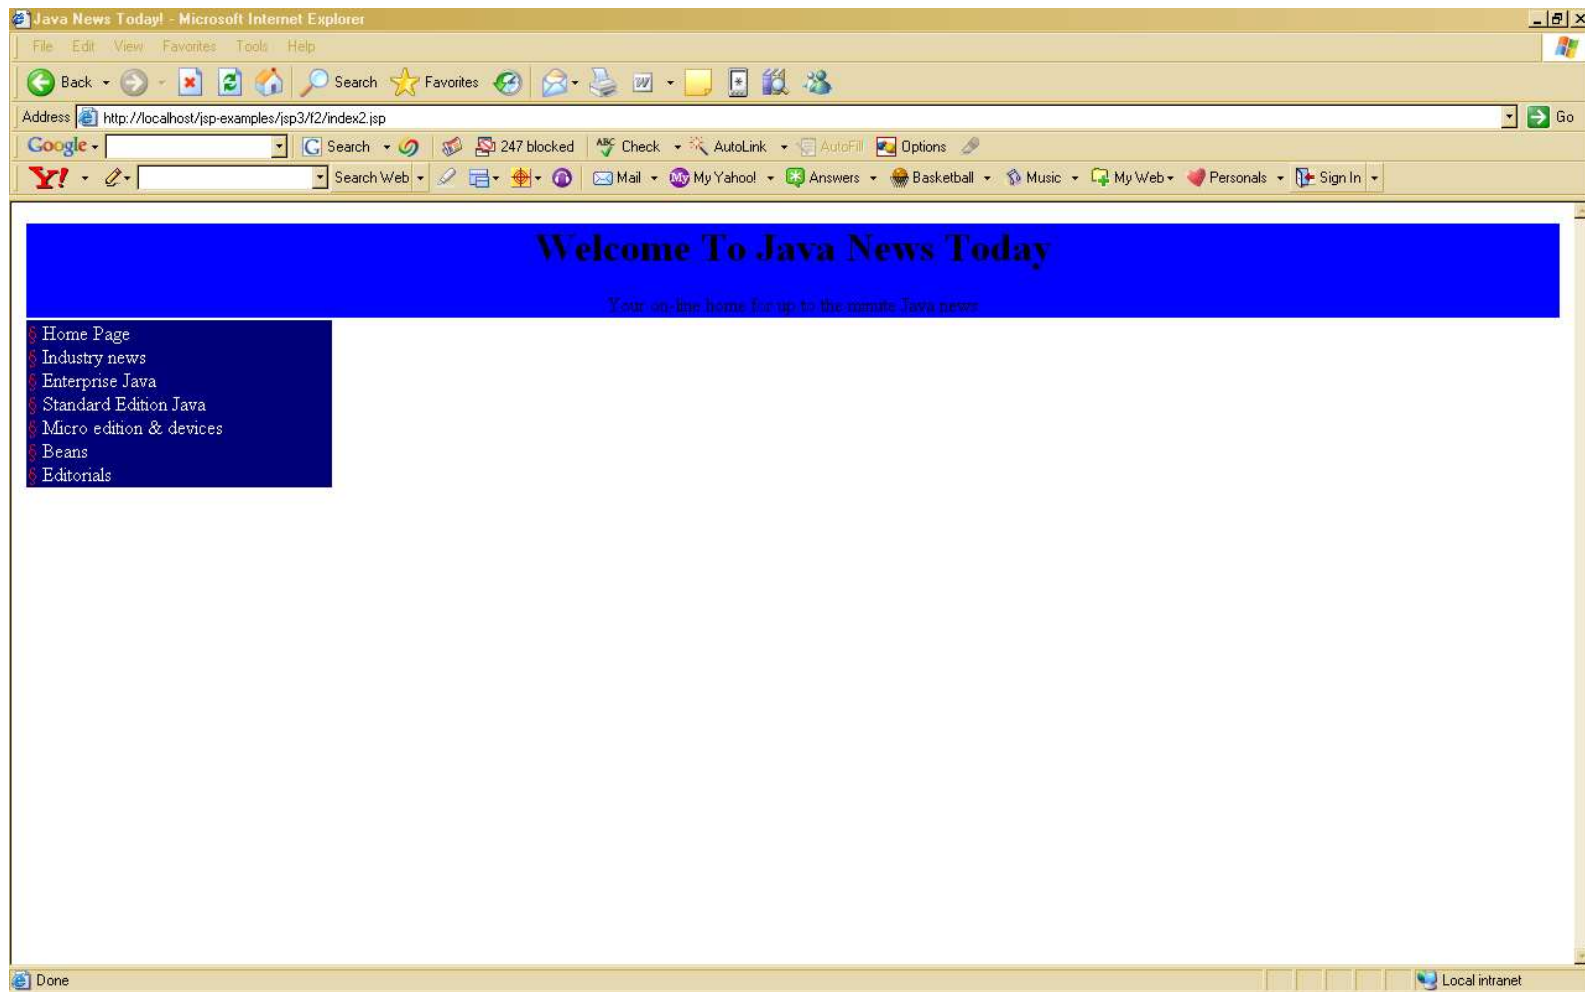

# Simple JSPs

- Let us see the following example how to do **Templating** through the use of **include directive**
- Example :
  - <http://localhost/jsp-examples/jsp3/f2/index2.jsp>

# Simple JSPs

➤ Here is the output ...

# Simple JSPs

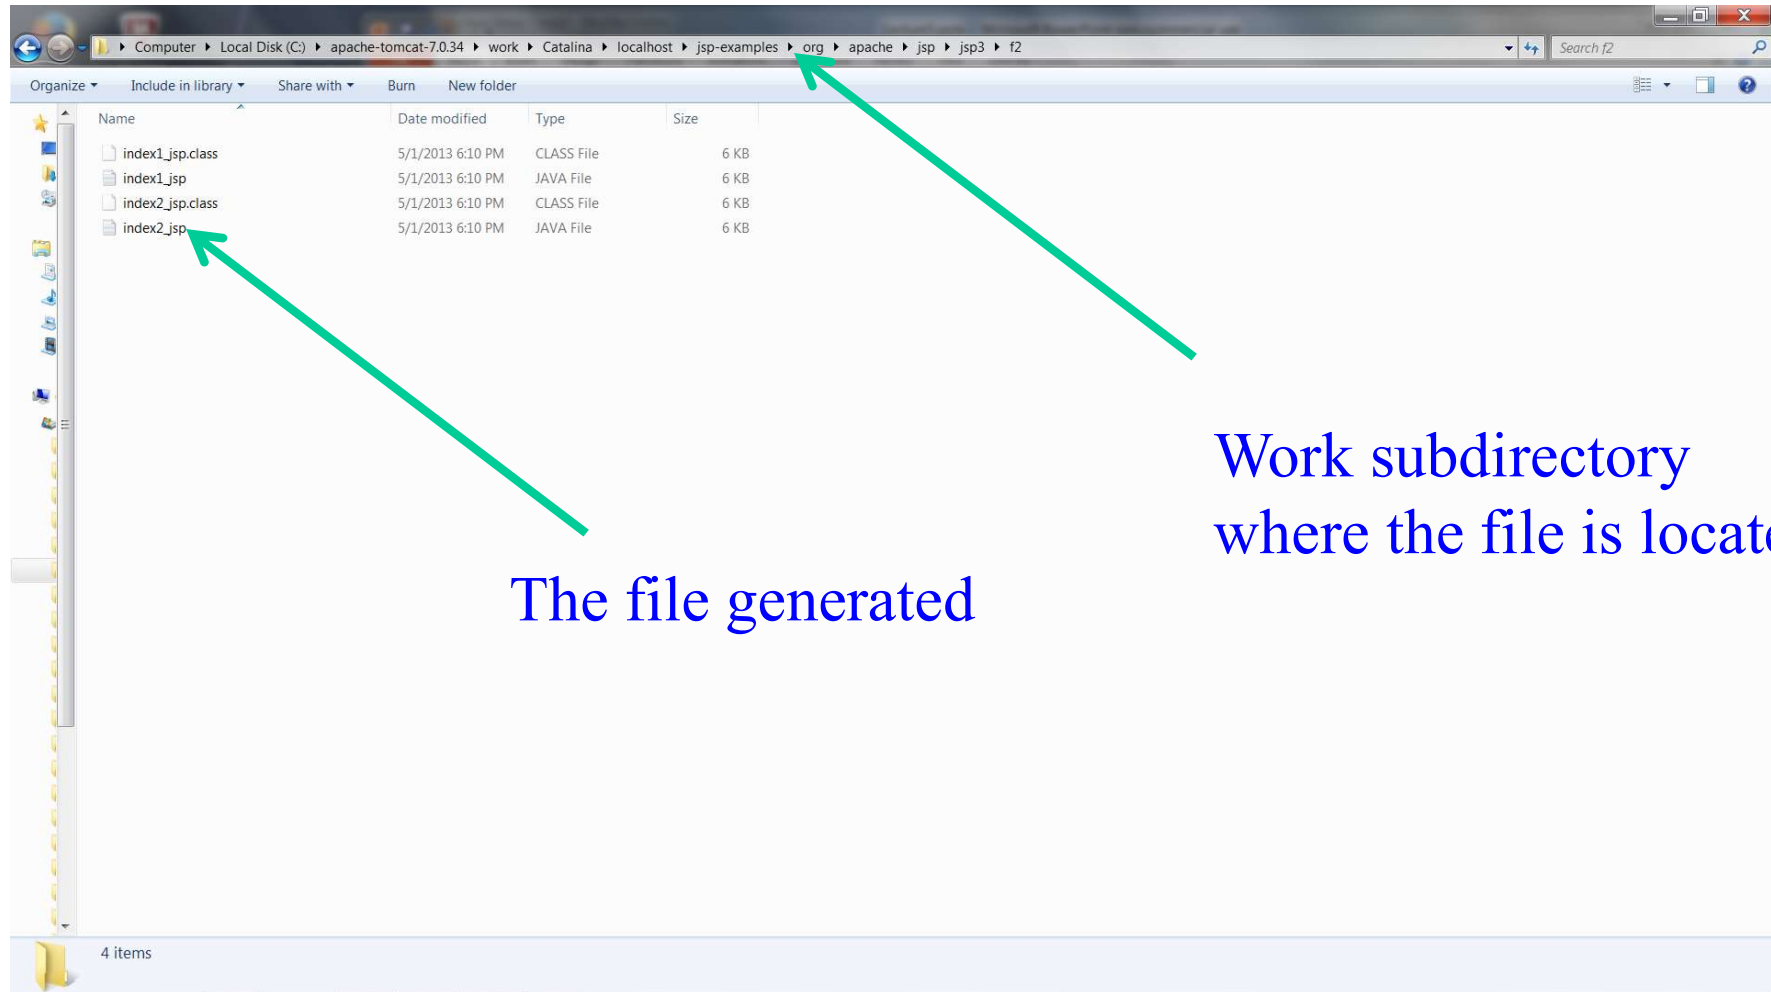

The index2.jsp included 2 files:

1. header.jsp
2. navigation.jsp

# Simple JSPs

When the jsp engine encounters the include tag the jsp engine will load the header.jsp and the navigation.jsp into index2.jsp file

# Code Generated by Tomcat for index2.jsp

# Types of JSP Scripting Elements

- JSP scripting elements let you insert Java code into the servlet that will be generated from the JSP page. There are three forms:
  1. **Expressions** of the form `<%= Java Expression %>`, which are evaluated and inserted into the servlet's output.
  2. **Scriptlets** of the form `<% Java Code %>`, which are inserted into the servlet's `_jspService` method (called by service).
  3. **Declarations** of the form `<%! Field/Method Declaration %>`, which are inserted into the body of the servlet class, outside any existing methods.

# JSP Tags

- Two formats:

`<% ... %>`

or

`<jsp: ... > </jsp:..>`

# Simple JSPs

- Now we shall look at some of the JSP tags

- **Comments**

`<%-- ...text...--%>`

- JSP comments are stripped out by the JSP engine at translation time. Consequently, they never appear in the final servlet and are never sent to the end user. Comments are used to indicate what is the code used for.

# Simple JSPs

- **Declarations**

**<%! Type varname; %>**

**<%! Return type methodname(argument1,argument2....){}%>**

- Declarations are used to add variables or methods to a jsp. Anything in a declaration is added to the resulting servlet at the class level.
- For variables, the declaration means that there will typically be one instance of the variable shared across all requests.

# Simple JSPs

- **Expressions**

**<%= expression %>**

The expression tag places printable form of a Java expression into the output of a page. Expressions may be anything from a simple variable to a method call to a complex mathematical form involving multiple terms.

# Simple JSPs

- **Scriptlets**

**<%....java code...%>**

Scriptlets allow arbitrary java code, to be placed in a JSP. For the most part such code should reside in beans and other classes, but there are times when placing it in a page is unavoidable. Complex logic can be added to pages by surrounding regions of text with scriptlets, where one scriptlet ends with an open brace and a second one provides the matching close.

# Simple JSPs

- **Include Directive**

**<%@ include file=" " %>**

The include directive adds the text of one jsp or other file to another file at translation time.

The effect is exactly as if the author had used an editor to paste the included file into the primary one.

# JSP Expressions

- A JSP expression is used to insert values directly into the output. It has the following form:
  - `<%= Java Expression %>`
- The expression is evaluated, converted to a string, and inserted in the page.
- This evaluation is performed at runtime (when the page is requested) and thus has full access to information about the request.
- For example, the following shows the date/time that the page was requested.
  - **Current time:** `<%= new java.util.Date() %>`

# JSP Expressions

- **Predefined Variables**
  - To simplify these expressions, you can use a number of predefined variables (or “implicit objects”).
  - The system uses these names as local variables in `_jspService` (the method that replaces `doGet` in servlets that result from JSP pages).

# JSP Expressions

- The most important **Predefined Variables** are :
  - **request**, the `HttpServletRequest`.
  - **response**, the `HttpServletResponse`.
  - **session**, the `HttpSession` associated with the request
  - **out**, the `Writer` (a buffered version of type `JspWriter`) used to send output to the client.
  - **application**, the `ServletContext`. This is a data structure shared by all servlets and JSP pages in the Web application and is good for storing shared data.

# JSP Expression

- <http://localhost/jsp-examples/Expressions.jsp>

## JSP Expressions

- Current time: Tue Oct 15 18:21:43 CDT 2013
- Server: Apache Tomcat/7.0.34
- Session ID: 774B12D335891617C87290FF25AC20A0
- The testParam form parameter: null

# JSP Expression

- <http://localhost/jsp-examples/Expressions.jsp>

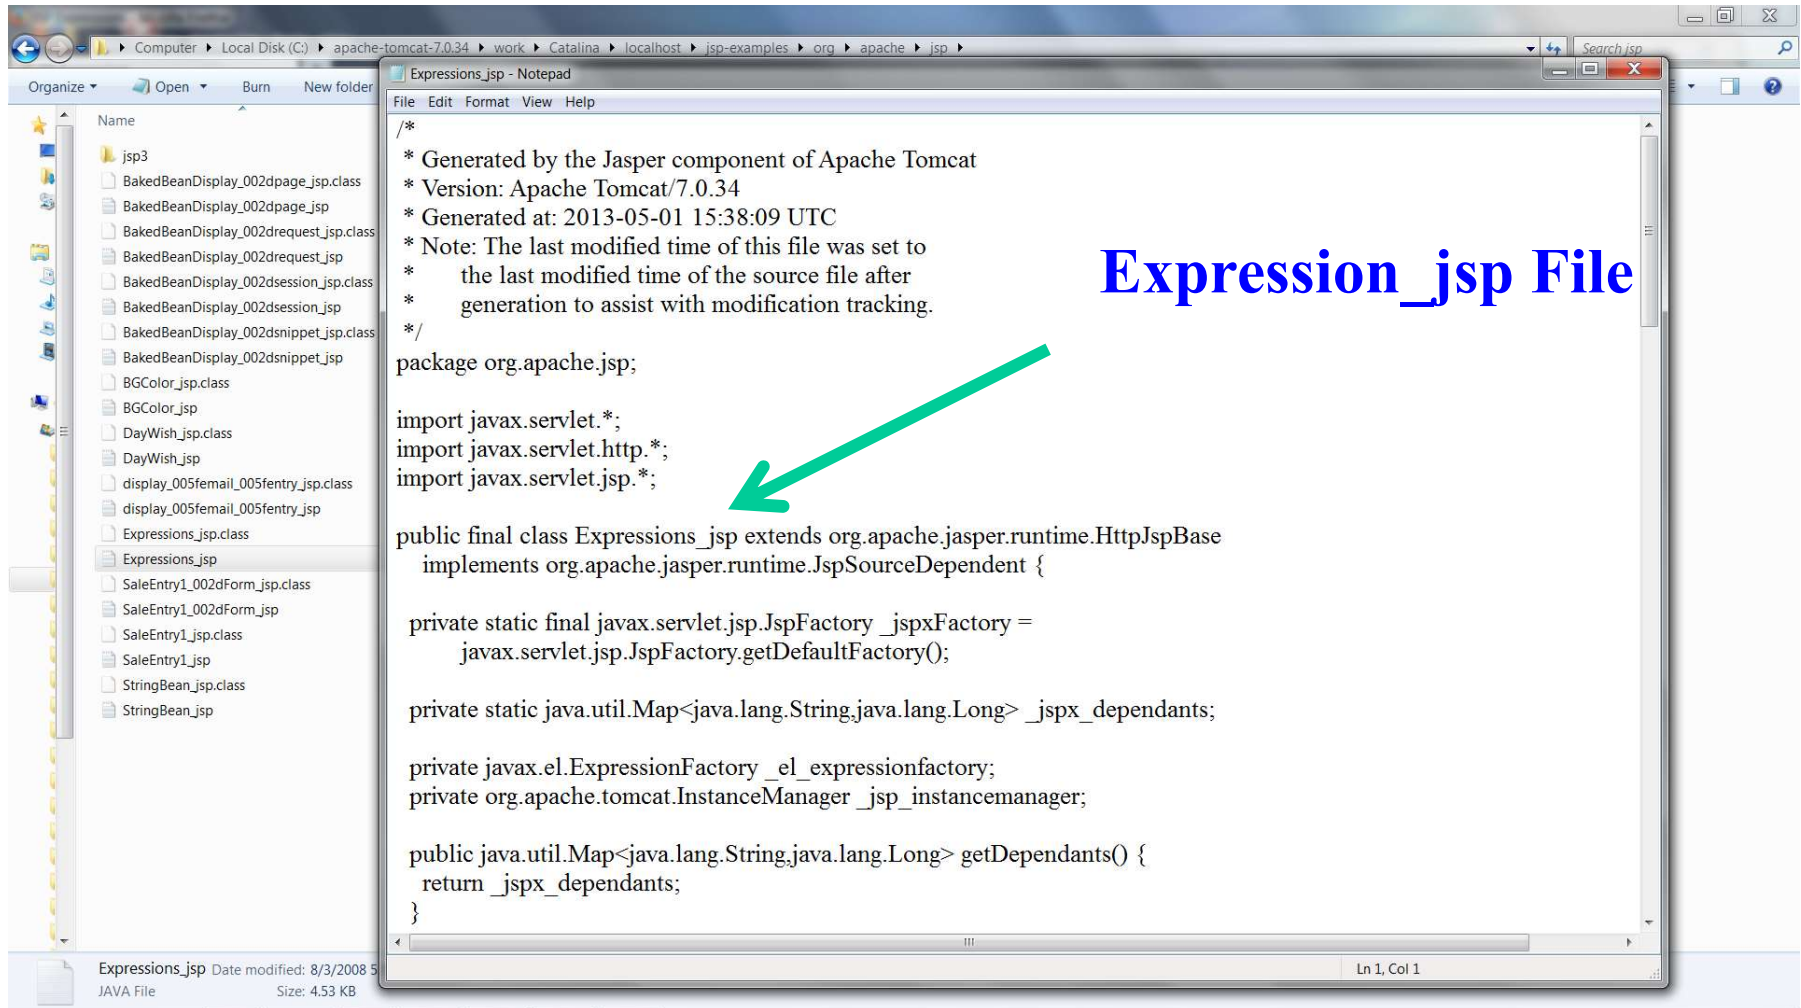

## JSP Expressions

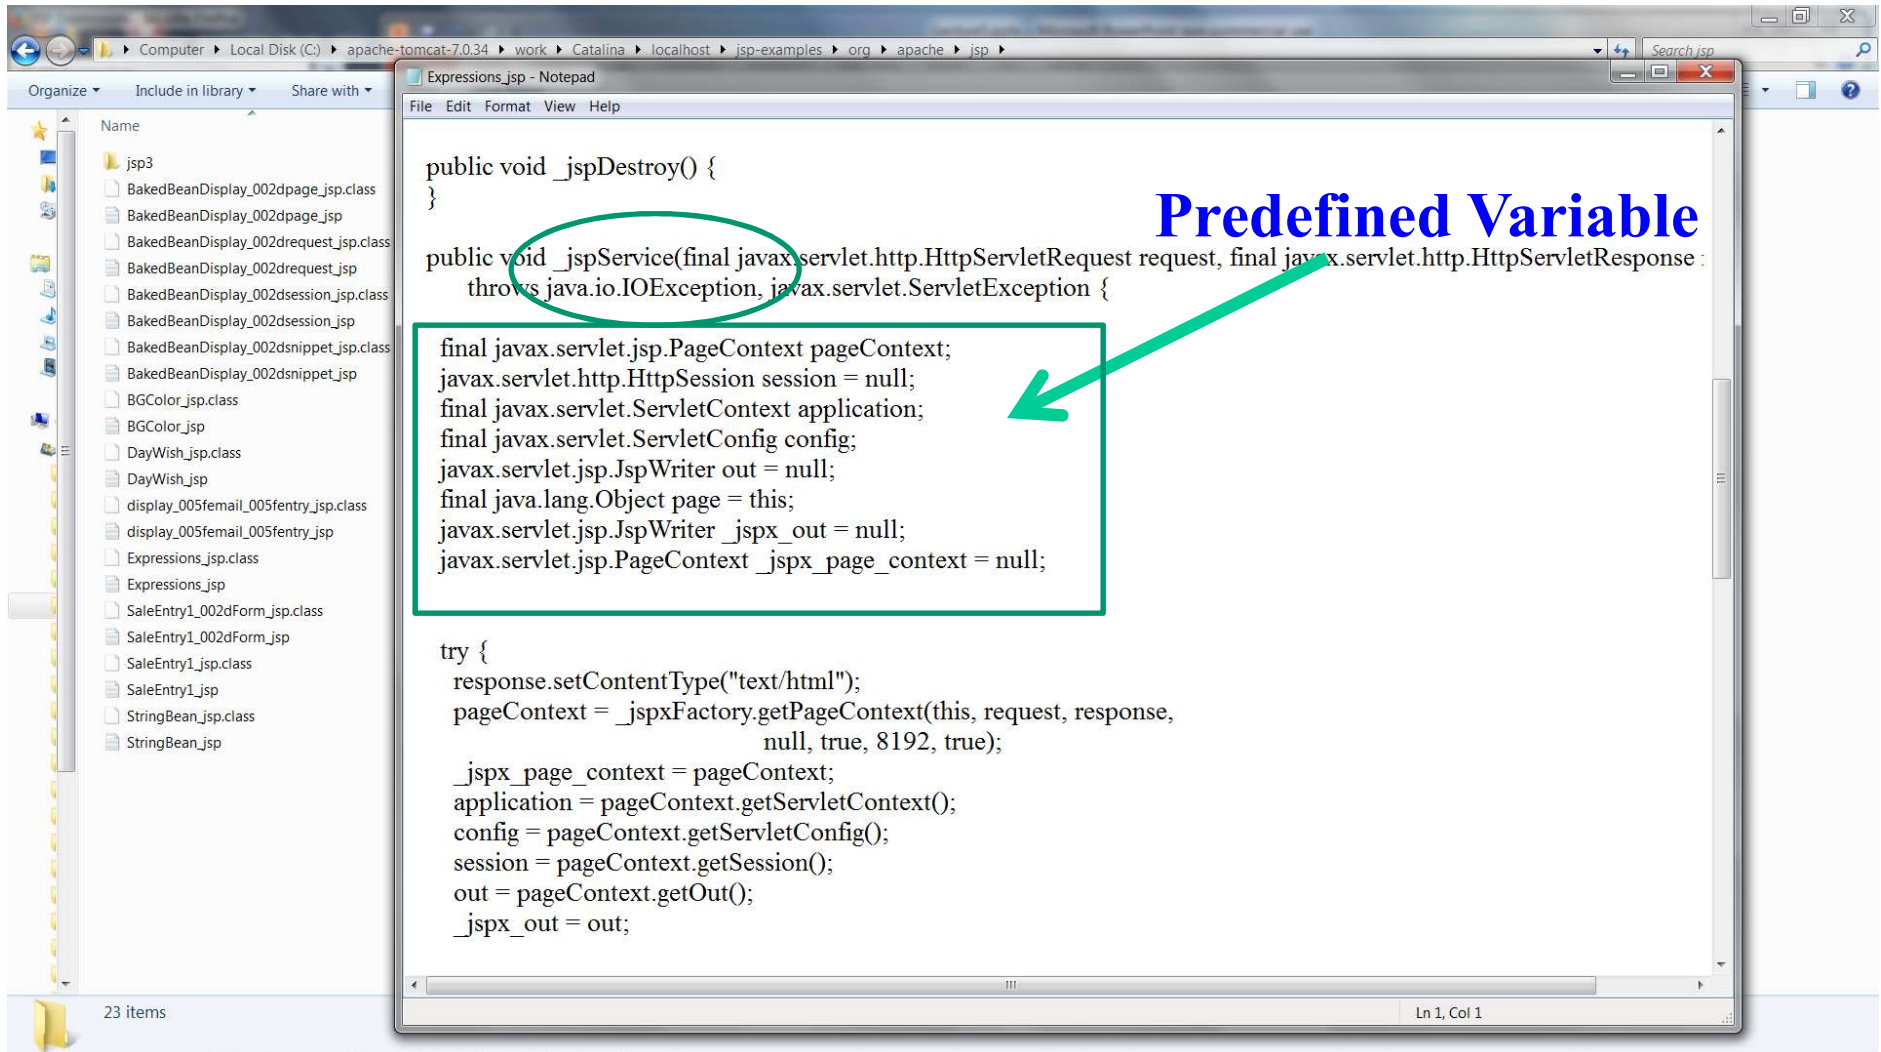

- Current time: Tue Oct 15 18:24:45 CDT 2013
- Server: Apache Tomcat/7.0.34
- Session ID: 774B12D335891617C87290FF25AC20A0
- The testParam form parameter: HelloBader

**testParam = HelloBader**

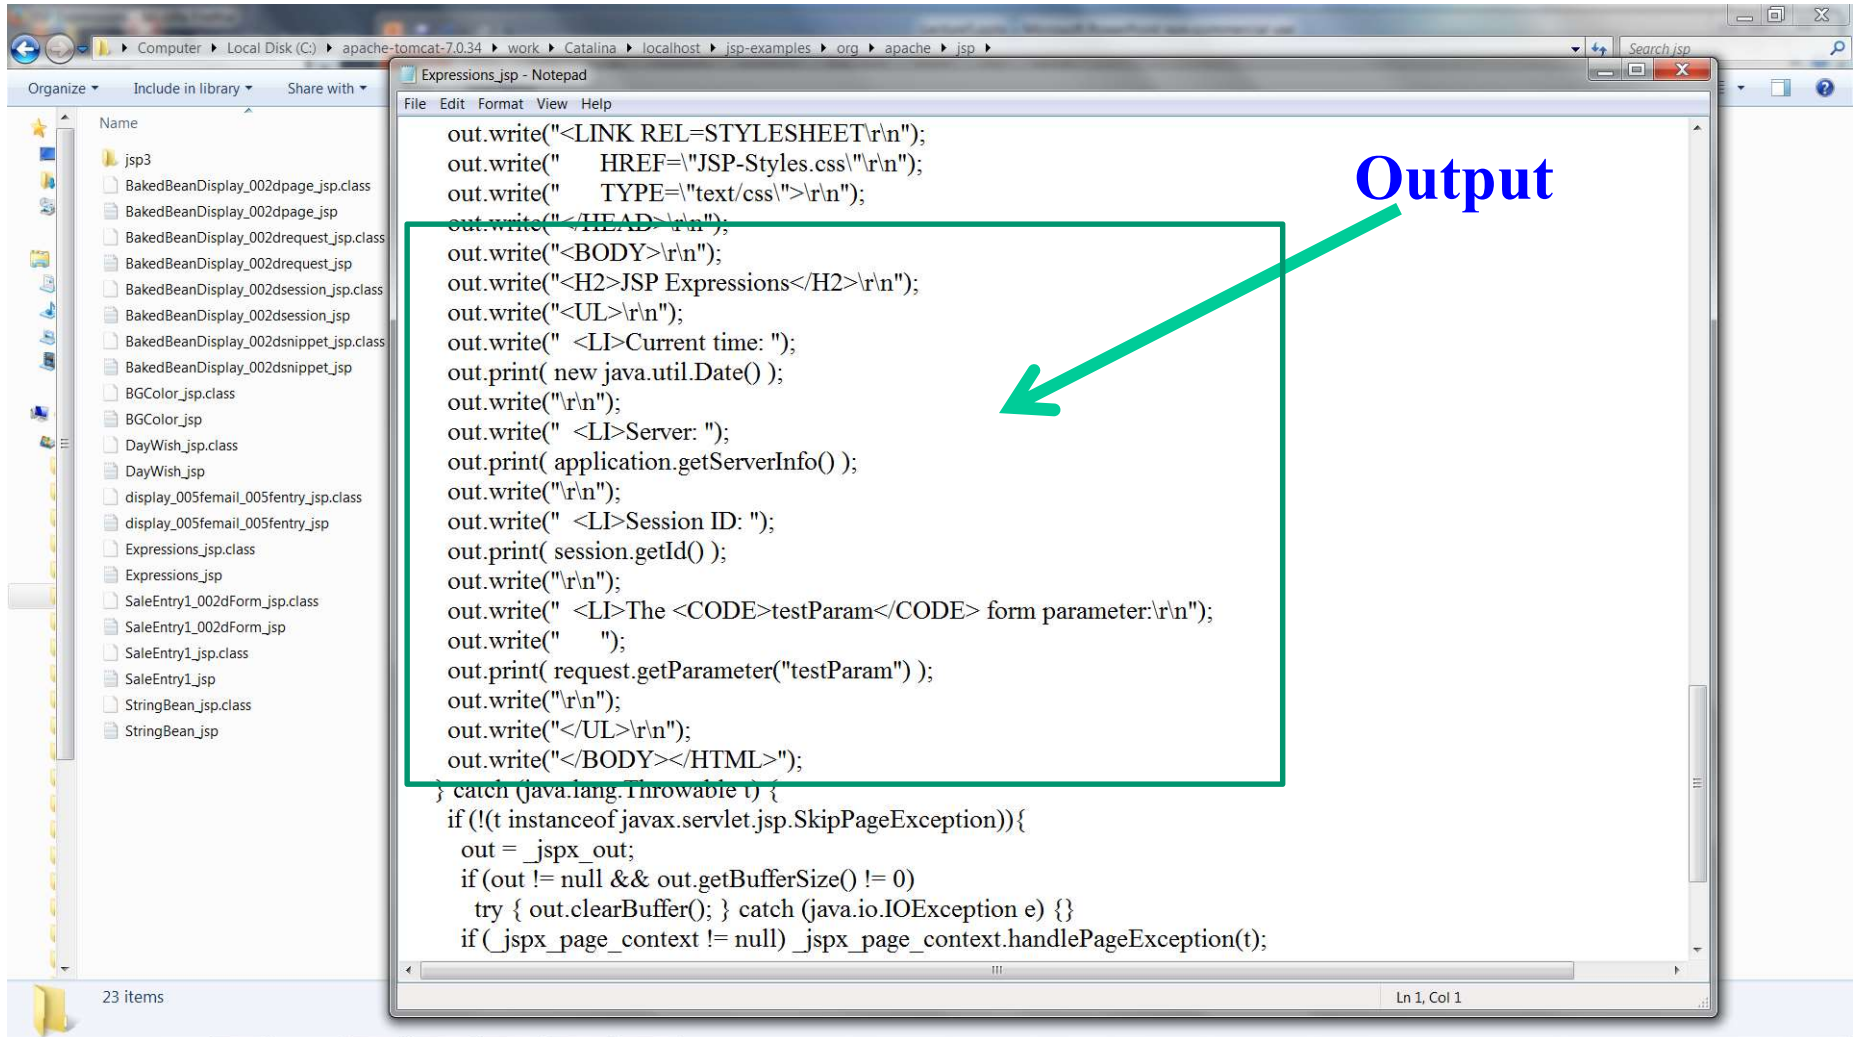

# Code Generated by Tocamt for <http://localhost/jsp-examples/Expressions.jsp>

# Code Generated by Tocamt for <http://localhost/jsp-examples/Expressions.jsp>

# Code Generated by Tocamt for <http://localhost/jsp-examples/Expressions.jsp>

The screenshot displays a web browser window showing the output of the `Expressions.jsp` page. The output is an HTML document with a link to `JSP-Styles.css`, a heading `JSP Expressions`, and a list containing the current time, server information, and session ID. A green box highlights the HTML output in the browser, and a green arrow points from the word **Output** to this box.

```
out.write("<LINK REL=STYLESHEET\r\n");
out.write("    HREF=\"JSP-Styles.css\"\r\n");
out.write("    TYPE=\"text/css\"\r\n");
out.write("</HEAD>\r\n");
out.write("<BODY>\r\n");
out.write("<H2>JSP Expressions</H2>\r\n");
out.write("<UL>\r\n");
out.write("  <LI>Current time: ");
out.print( new java.util.Date() );
out.write("\r\n");
out.write("  <LI>Server: ");
out.print( application.getServerInfo() );
out.write("\r\n");
out.write("  <LI>Session ID: ");
out.print( session.getId() );
out.write("\r\n");
out.write("  <LI>The <CODE>testParam</CODE> form parameter:\r\n");
out.write("    ");
out.print( request.getParameter("testParam") );
out.write("\r\n");
out.write("</UL>\r\n");
out.write("</BODY></HTML>");
} catch (java.lang.Throwable t) {
    if (!(t instanceof javax.servlet.jsp.SkipPageException)){
        out = _jspx_out;
        if (out != null && out.getBufferSize() != 0)
            try { out.clearBuffer(); } catch (java.io.IOException e) {}
        if (_jspx_page_context != null) _jspx_page_context.handlePageException(t);
    }
}
```

# JSP Expression

We can use the expression tag to do some mathematical calculations

```
<HTML>
```

```
<BODY>
```

```
1 + 1 equals <%= 1 + 1 %>
```

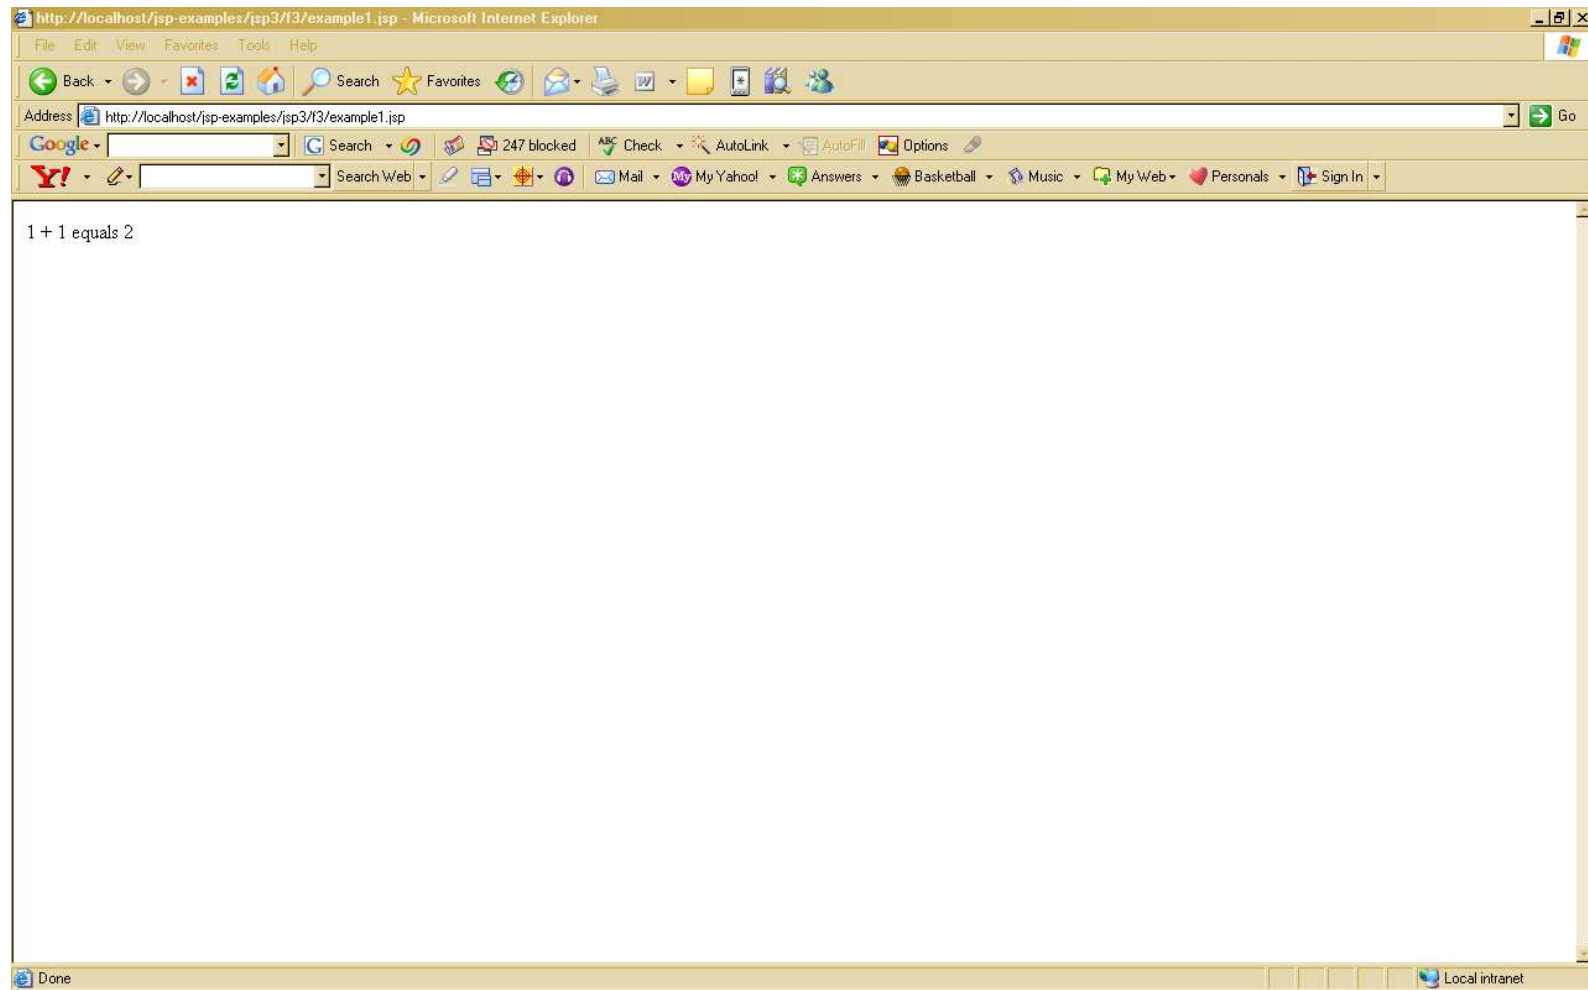

```
</BODY>
```

```
</HTML>
```

❖ <http://localhost/jsp-examples/jsp3/f3/example1.jsp>

# JSP Expression

Here is the output ...

# JSP Implicit Object

- The implicit object **request** is an important one for passing information from the browser to the server

```
<HTML>
```

```
<BODY>
```

```
Hello user! You are using a computer  
called <%= request.getRemoteHost() %>!
```

```
</BODY>
```

```
</HTML>
```

➤ Here is the page after pressing the GO button ...

# Scriptlet

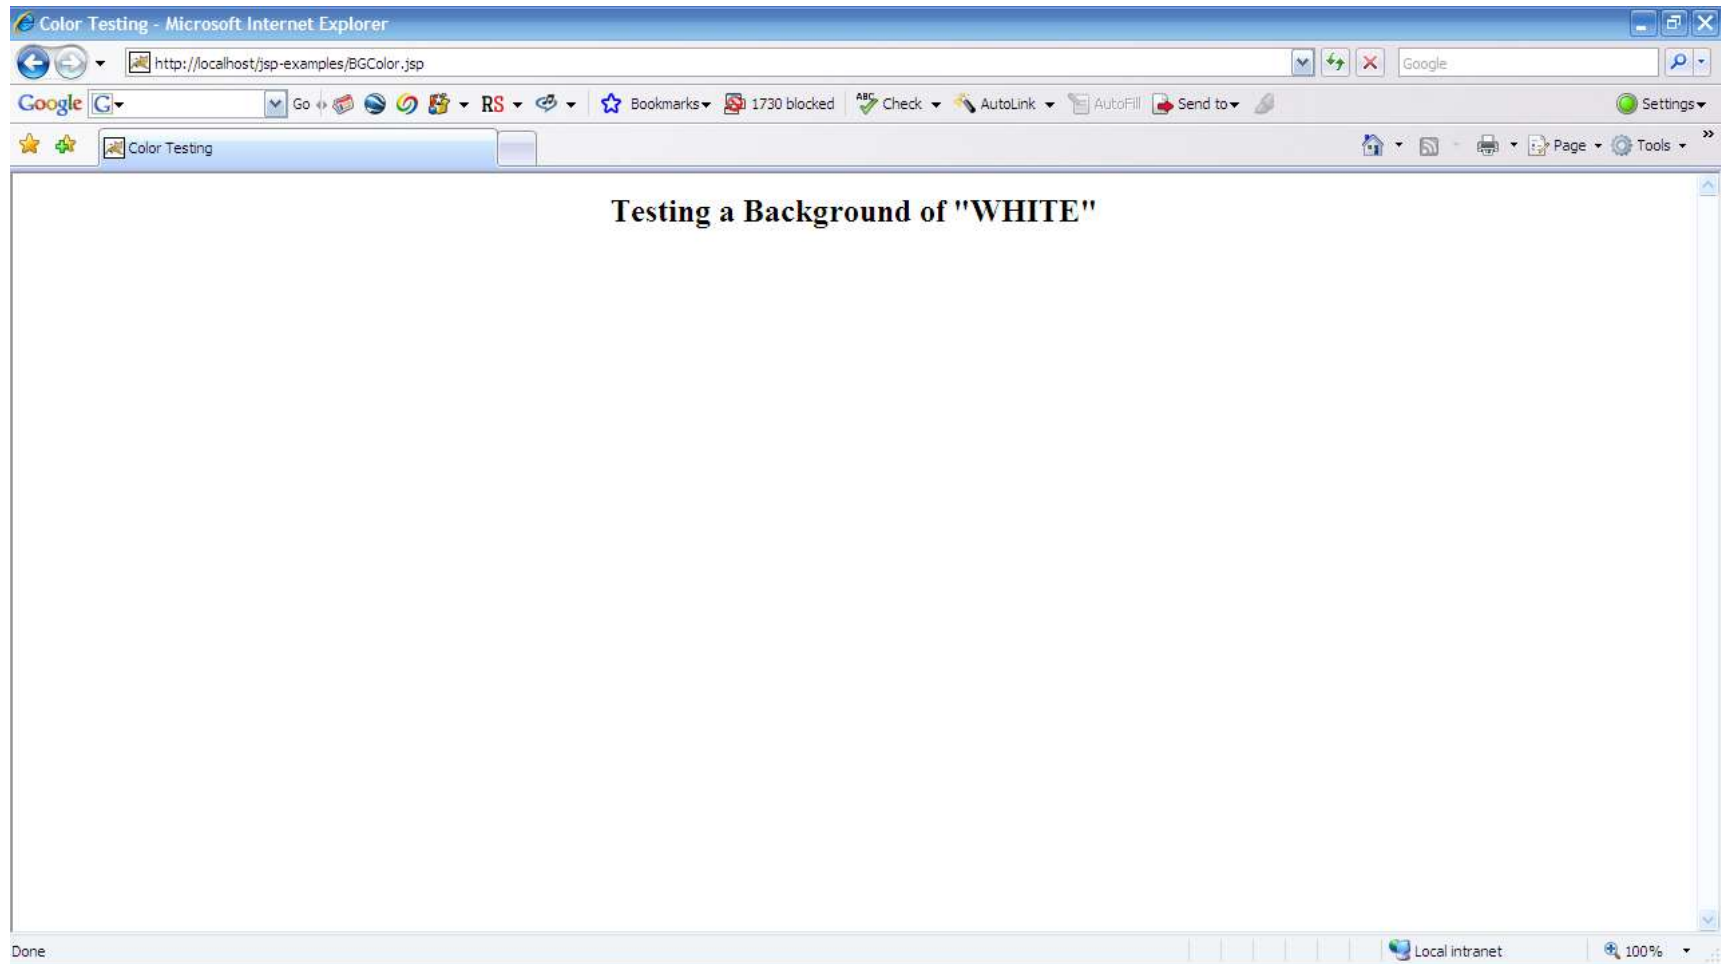

- If you want to do something more complex than output the value of a simple expression, JSP scriptlets let you insert arbitrary code into the servlet's `_jspService` method (which is called by service).
- Scriptlets have the following form:
  - `<% Java Code %>`
- Scriptlets have access to the same automatically defined variables as do expressions (request, response, session, out, etc.).
- So, for example, if you want to explicitly send output to the resultant page, you could use the out variable, as in the following example.

```
<%  
String queryData = request.getQueryString();  
out.println("Attached GET data: " + queryData);  
%>
```

# Scriptlet Example

- As an example of code that is too complex for a JSP expression alone, following example presents a JSP page that uses the bgColor request parameter to set the background color of the page.
- Simply using  
`<BODY BGCOLOR="<%= request.getParameter("bgColor") %>">`
- would violate the cardinal rule of reading form data: always check for missing or malformed data. So, we use a scriptlet instead.
- <http://localhost/jsp-examples/BGColor.jsp>

# Scriptlet Example

# Scriptlet Example

# Scriptlet Example

# Using Scriptlets to Make Parts of the JSP Page Conditional

- Scriptlets are used to conditionally output HTML or other content that is *not* within any JSP tag.
- The key to this approach are the facts that
  - (a) code inside a scriptlet gets inserted into the resultant servlet's `_jspService` method (called by service) *exactly* as written and
  - (b) that any static HTML (template text) before or after a scriptlet gets converted to print statements.
- <http://localhost/jsp-examples/DayWish.jsp>

# Using Scriptlets to Make Parts of the JSP Page Conditional

# Using Scriptlets to Make Parts of the JSP Page Conditional

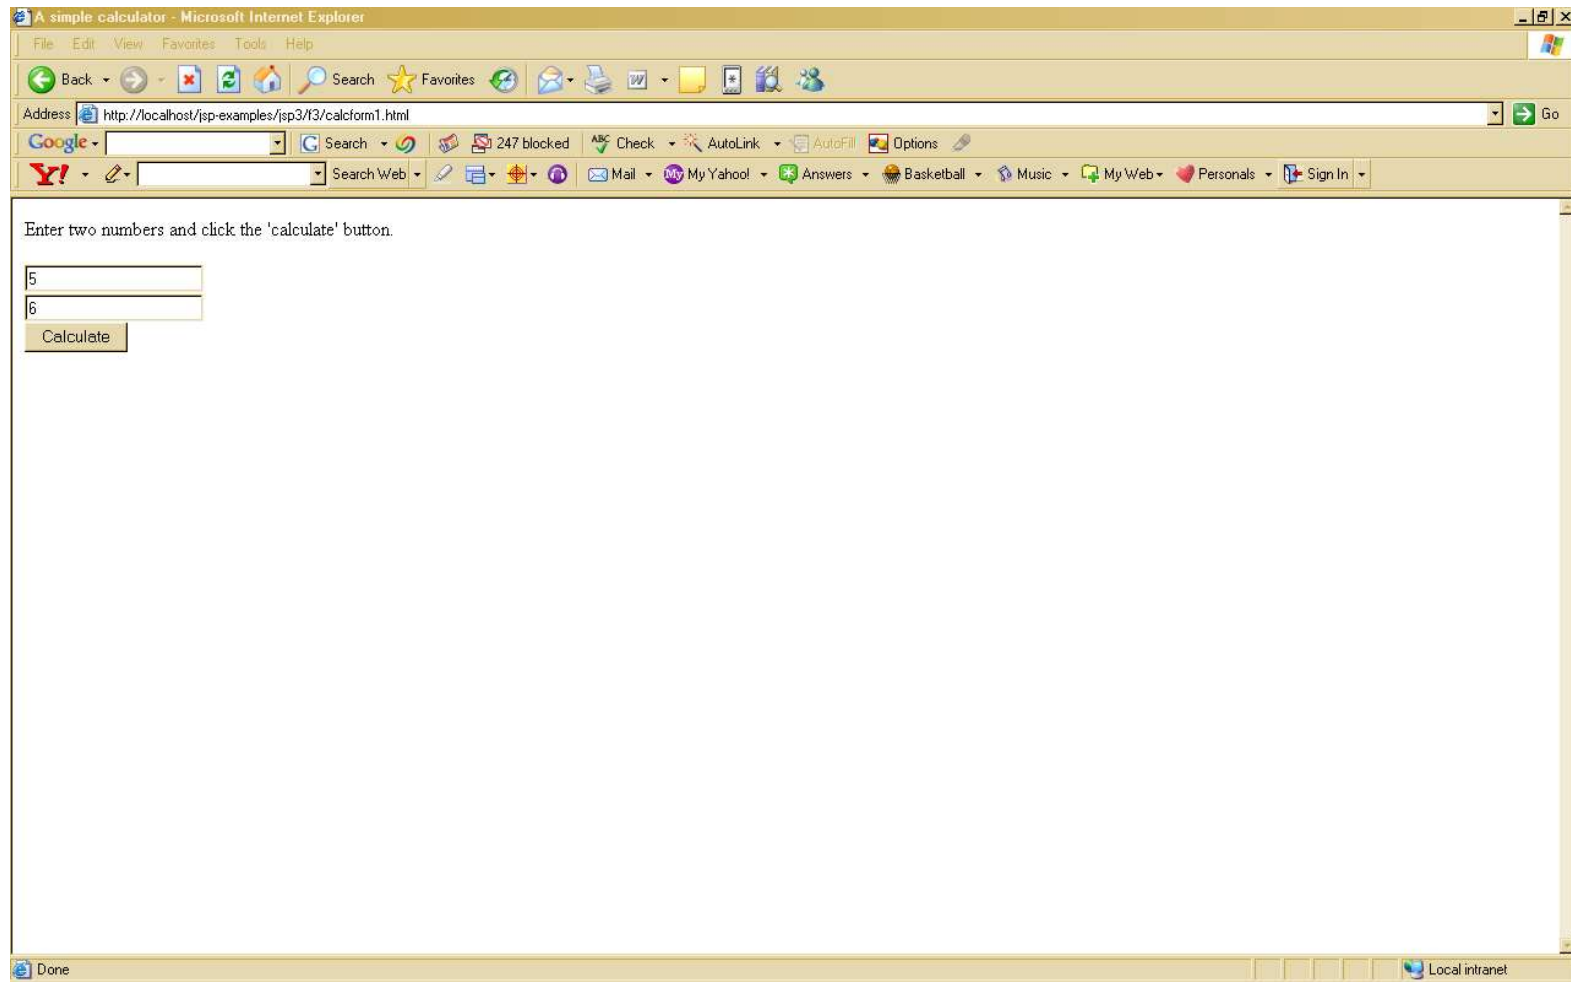

# Simple Calculator

➤ We want the user to enter 2 values and then call `request.getParameter("parameter name")` and then find the sum of the 2 values. Pay careful attention to “+” it is concatenation and we want to add 2 numbers, so we need to use `Integer.parseInt( ... )`

# Simple Calculator

➤ Here is the page ...

# Simple Calculator

➤ Here is the page after pressing the Calculate button...

# Beans

## ➤ Why Use Beans?

- The use of JavaBeans components in JSP provides three advantages over scriptlets and JSP expressions that refer to normal Java classes:
  1. **No Java syntax.** By using beans, page authors can manipulate Java objects using only XML-compatible syntax: no parentheses, semicolons, or curly braces.
  2. **Simpler object sharing.** When you use the JSP bean constructs, you can much more easily share objects among multiple pages or between requests than if you use the equivalent explicit Java code.
  3. **Convenient correspondence between request parameters and object properties.** The JSP bean constructs greatly simplify the process of reading request parameters, converting from strings, and putting the results inside objects.

# Beans

- **Beans Coding Styles and Constraints**
  - **A bean class must have a zero-argument (default) constructor.** The default constructor will be called when JSP elements create beans.
  - **A bean class should have no public instance variables (fields).**
  - **Persistent values should be accessed through methods called `getXxx` and `setXxx`.**
    - The one exception to this naming convention is with boolean properties: they are permitted to use a method called `isXxx` to look up their values; So, for example, your Car class might have methods called `isLeased` and `setLeased`

# Beans

- **Use three main constructs** to build and manipulate JavaBeans components in JSP pages:
  - **jsp:useBean.** In the simplest case, this element builds a new bean. It is normally used as follows:
    - `<jsp:useBean id="beanName" class="package.Class" />`

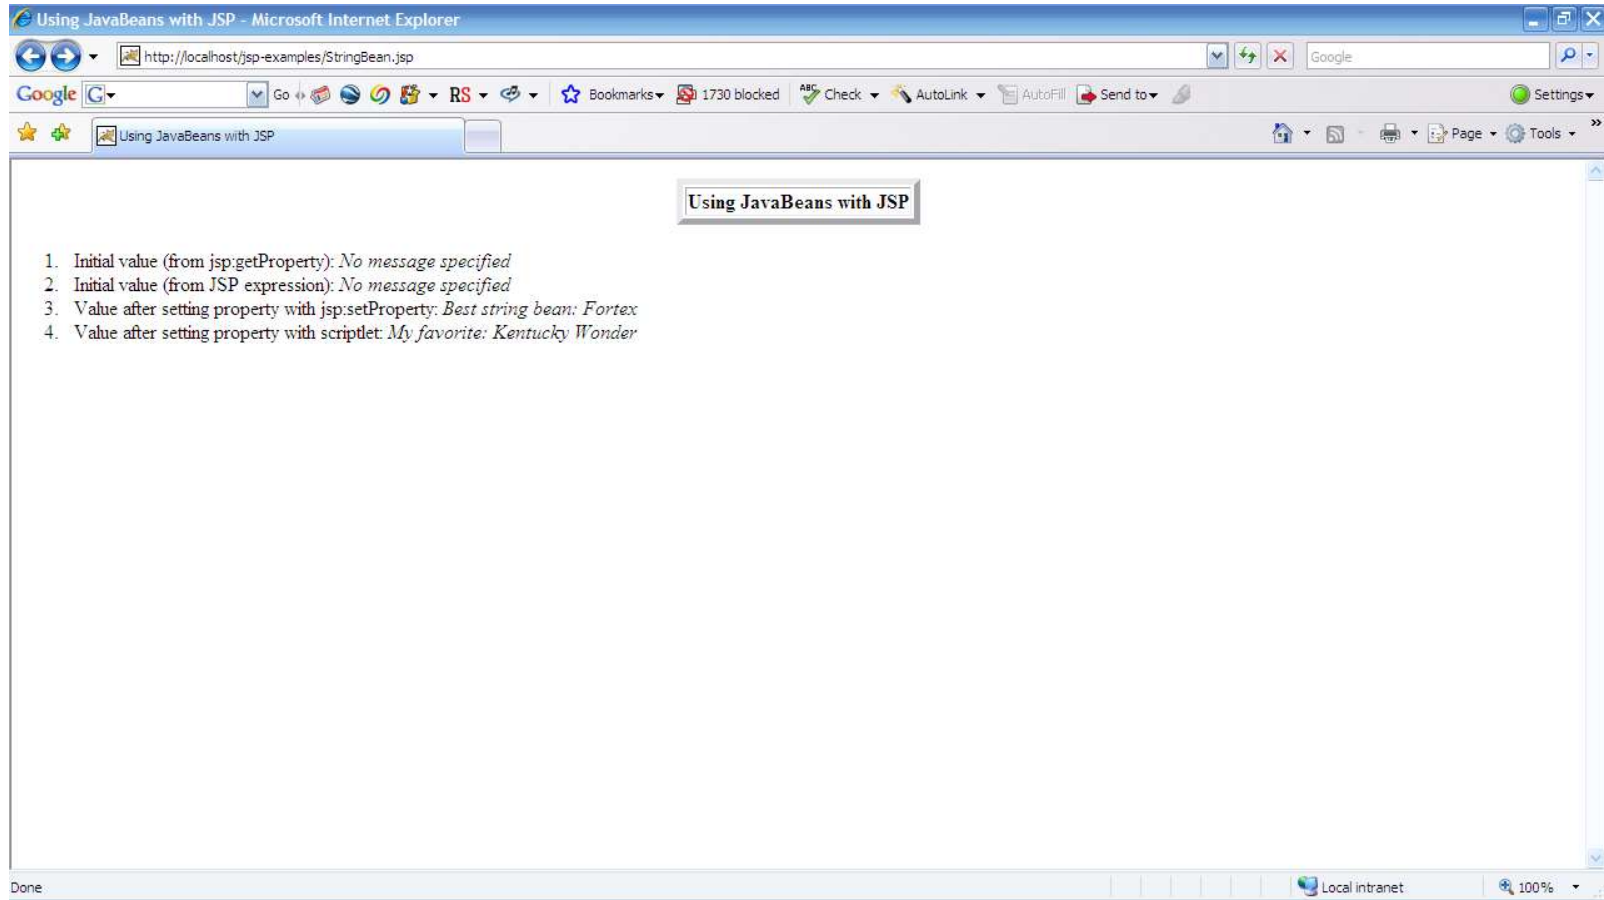

# Beans

- **jsp:getProperty.** reads and outputs the value of a bean property. Reading a property is a shorthand notation for calling a method of the form `getXxx`. This element is used as follows:
  - `<jsp:getProperty name="beanName" property="propertyName" />`
- **jsp:setProperty.** Modifies a bean property (i.e., calls a method of the form `setXxx`). It is normally used as follows:
  - `<jsp:setProperty name="beanName" property="propertyName" value="propertyValue" />`

# Example: StringBean

- Always put your Java Beans in Packages
- Following example presents a simple class called StringBean that is in the mybean package.
- <http://localhost/jsp-examples/StringBean.jsp>
  - Calls StringBean from
  - <C:\apache-tomcat-7.0.34\webapps\jsp-examples\WEB-INF\classes\mybean>

# Example: StringBean

# Beans

- A Bean is a black-box component
- Just follows a naming convention, for each variable x, there are 2 methods defined on the bean getX(), setX(..)
- JSP uses the following tags to declare and access a bean:

```
<jsp:useBean id="bean1" class="mybean.Bean1"/>
```

```
<jsp:getProperty name="bean1" property="currentTime"/>
```

# Beans

➤ Build your bean, Bean1.java, and save it in the following directory:

❖ **C:\apache-tomcat-7.0.34\webapps\jsp-examples\WEB-INF\classes\mybean**

➤ Let us see how we can call a bean from jsp

❖ <http://localhost/jsp-examples/jsp3/f4/beanexample1.jsp>

# Beans

➤ Here is the output of beanexample1.jsp

Here is some data that came from bean1:

- The name of this bean is: mybean
- The 7th prime number is: 17
- The current time is: 07:08 and 34 seconds

The information from a bean can be used anywhere on the page!

# Beans - Forms

- Let us see how we can build a bean that can access variables from a form
- Notice how we can pass the whole form parameters through the use of the wild character.
- Compile and save your bean at:
  - ❖ **C:\apache-tomcat-7.0.34\webapps\jsp-examples\WEB-INF\classes\calculatorBean\CalcBean**
- Let us see how we can call a bean from jsp
  - ❖ <http://localhost/jsp-examples/jsp3/f4/calcform.html>

# Beans - Forms

➤ Here is the page for:

<http://localhost/jsp-examples/jsp3/f4/calcfom.html>

Enter two numbers and click the 'calculate' button.

7	
9	
<input type="button" value="Calculate"/>	

# Beans - Forms

➤ Here is the page after pressing calculate button:

The sum of your two numbers is 16

# Setting Bean Properties:

- We use `jsp:setProperty` to set bean properties.
- `jsp:setProperty` takes three attributes:
  - **name** (which should match the id given by `jsp:useBean`),
  - **property** (the name of the property to change), and
  - **value** (the new value).
- Following example has:
  - <http://localhost/jsp-examples/SaleEntry1-Form.jsp> which calls
    - <http://localhost/jsp-examples/SaleEntry1.jsp> which calls
      - <C:\apache-tomcat-7.0.34\webapps\jsp-examples\WEB-INF\classes\mybean\SaleEntry>

# Setting Bean Properties:

The screenshot shows a Mozilla Firefox browser window with the title 'Invoking SaleEntry1.jsp - Mozilla Firefox'. The address bar displays 'localhost/jsp-examples/SaleEntry1-Form.jsp'. The page content includes a title 'Invoking SaleEntry1.jsp' in a box, followed by three input fields: 'Item ID: a1234', 'Number of Items: 7', and 'Discount Code: 0.9'. Below these fields is a 'Show Price' button. The browser's status bar at the bottom shows 'Secure Search' and 'McAfee'.
